EuroCrypt – May 23rd, 2019

INRIA, and
Horst Görtz Institut für IT Sicherheit, Ruhr-Universität Bochum

Anne Canteaut, Virginie Lallemand, Gregor Leander, Patrick Neumann, and Friedrich Wiemer

- Whitened Swap-Or-Not Construction developed by Hoang et al. and Tessaro
- Way of building block ciphers
- As this is one of the few talks here at EuroCrypt about block ciphers, we will start simple

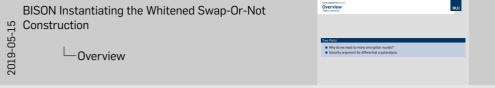

RUB

Overview Topics covered

Two Parts

- Why do we need so many encryption rounds?
- Security argument for differential cryptanalysis.

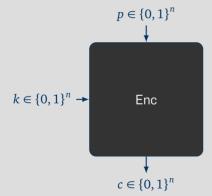

- Talk mainly about two parts of the paper:
 - Why do we need so many rounds (easy to understand argument)
 - Security against differential cryptanalysis
 (again relative simple argument that gives strong security here)

Block Ciphers

Encrypt plaintext in blocks p of n bits, under a key of n bits:

BISON Instantiating the Whitened Swap-Or-Not Construction 년 The WSN construction

under a key of n bits:

- Block ciphers encrypt *blocks* of *n*-bit inputs under an *n*-bit master key
- As a basic cryptographic primitive, we need special modes of operations, if the data to be encrypted is not of exactly *n*-bit length.
- This we do not consider here, instead we want to look at how to build this black box.
- Typicall approach is an SPN structure, where key-addition, S-box layer and a linear layer are iterated over several rounds.
- Relatively well understood

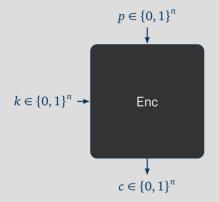

—Block Ciphers

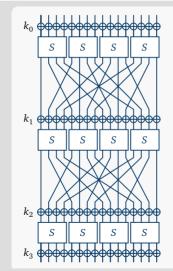

- Good security arguments against known attacks
- There are some problems: differentials and linear hull effects

BISON Instantiating the Whitened Swap-Or-Not Construction - The WSN construction

The WSN construction

- Lets take a look at the WSN construction (simplified).
- Again, an iterated round function, where the input is fed into from the left.
- Next, a Boolean function decides if either the round key k is xored onto the input, or nothing happens.
- The result is the updated state, respective the output of the round.
- In other words, x, and k are both n-bit strings and f is an n-bit Boolean function.
- The round output y is either x + k if $f_k(x) = 1$ or just x in the other case.
- So why is this nice?

The WSN construction

- Lets take a look at the WSN construction (simplified).
- Again, an iterated round function, where the input is fed into from the left.
- Next, a Boolean function decides if either the round key k is xored onto the input, or nothing happens.
- The result is the updated state, respective the output of the round.
- In other words, x, and k are both n-bit strings and f is an n-bit Boolean function.
- The round output y is either x + k if $f_k(x) = 1$ or just x in the other case.
- So why is this nice?
- Tessaro was able to show that this construction, when iterated over $\Theta(n)$ rounds, achieves *Full Domain* security (what ever that means).

- Sounds all very great.
- So from a practitioners point of view the natural next point is: lets implement it.

Construction

- $f_k(x) := ?$
- Key schedule?
- lacksquare $\Theta(n)$ rounds?

Theoretical vs. practical constructions

BISON Instantiating the Whitened Swap-Or-Not
Construction
The WSN construction
An Implementation

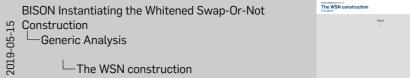

- Sounds all very great.
- So from a practitioners point of view the natural next point is: lets implement it.
- But uggh...
- How does this Boolean function f_{ν} actually looks like?
- What about a key schedule? How do we derive the round keys?
- And how many are $\Theta(n)$ rounds?
- So, from a theoretical point of view we have a nice construction.
- But from a practical point of view it is basically useless.
- OK. let us fix this.

The WSN construction Encryption

Rational 1 & 2: WSN is *slow* in practice!

The advantage?

Differential Cryptanalysis!

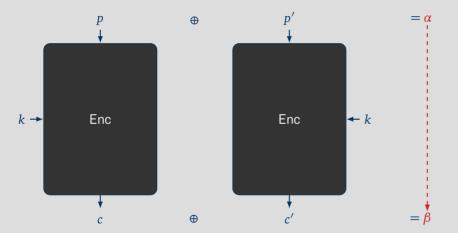

BISON Instantiating the Whitened Swap-Or-Not Construction -Generic Analysis

A genus of the WSN family: BISON Differential Cryntanalysis

A genus of the WSN family: BISON

- A guick recap and implications for any WSN instance.
- Rationale 2 basically tells us, we have to use bent functions.
- Thats nice, as those functions are quite well understood and already well scrutinised.
- Also, this is the reason for the name: Bent Whitened Swap-Or-Not
- But, and thats not so nice...
- n iterations of a round function that depends on all bits will be slow
- Let me repeat this (Reviewer 2 argued that we should optimise more): No matter how good we will optimise this: it will be slow
- For example, assume you can do one round in one clock cycle, this is still an order of magnitude slower than AES.
- So, why should we care about any instance?
- All hope is not lost, let's have a look at differential cryptanalysis!

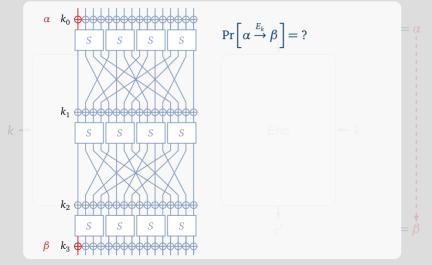

BISON Instantiating the Whitened Swap-Or-Not Construction - Differential Analysis

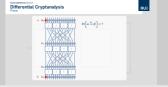

- For differential cryptanalysis, interested in propagation of input difference α to output difference β .
- Doing this in general at this abstraction level is a very hard problem.

- For differential cryptanalysis, interested in propagation of input difference α to output difference β .
- Doing this in general at this abstraction level is a very hard problem.
- To say anything, we usually look for single so called *trails* through the inner building blocks.
- Now, computing the probability of one such trail is actually doable.
- But, trails can go several alternative ways through non-linear parts, thus we have to cope with a branching effect...
- And eventually, several of these trails cluster in a so called differential.
- While in this example it is still feasible, computing the *exact* probability in a real cipher is not.
- We thus have to restrain on bounding or approximating this probability.
- In the end, tight bounds for differentials over several rounds remain an open (but important!) problem.
- For BISON our aim is to give exactly this: a tight bound for any differential over several rounds.

RUB

Differential Cryptanalysis One round

Theorem

For one round of BISON the probabilities are:

$$\Pr_{x} \left[\alpha \to \beta \right] = \begin{cases} 1 & \text{if } \alpha = \beta = k \text{ or } \alpha = \beta = 0 \\ \frac{1}{2} & \text{else if } \beta \in \{\alpha, \alpha + k\} \\ 0 & \text{else} \end{cases}$$

- We start by understanding the differential one round behaviour.
- For the three possible cases, let us look at what differences are actually possible.

Differential CryptanalysisOne round

RUB

Theorem

For one round of BISON the probabilities are:

$$\Pr_{x} \left[\alpha \to \beta \right] = \begin{cases} 1 & \text{if } \alpha = \beta = k \text{ or } \alpha = \beta = 0\\ \frac{1}{2} & \text{else if } \beta \in \{\alpha, \alpha + k\}\\ 0 & \text{else} \end{cases}$$

Possible differences

$$x + f_k(x) \cdot k$$

$$\oplus x + \alpha + f_k(x + \alpha) \cdot k$$

$$= \alpha + (f_k(x) + f_k(x + \alpha)) \cdot k$$

Properties of f_k

$$f_{\nu}(x) = f_{\nu}(x+k) \tag{1}$$

BISON Instantiating the Whitened Swap-Or-Not Construction Differential Analysis

- We start by understanding the differential one round behaviour.
- For the three possible cases, let us look at what differences are actually possible.
- Remember that one round computes the output as $x + f_k(x) \cdot k$.
- With the input difference α we get as possible output differences $\beta \in \{0, \alpha, k, \alpha + k\}$.
- For decryption we need that x and x + k are mapped to the same value by f_{ν}
- Thus, $\beta = \alpha$ with probability one, if and only if $\alpha = k$ or $\alpha = 0$
- ullet If eta is not one of the above four values, such an input/output pair cannot occur, thus the probability is zero.

RUB

Theorem

For one round of BISON the probabilities are:

$$\Pr_{x} \left[\alpha \to \beta \right] = \begin{cases} 1 & \text{if } \alpha = \beta = k \text{ or } \alpha = \beta = 0\\ \frac{1}{2} & \text{else if } \beta \in \{\alpha, \alpha + k\}\\ 0 & \text{else} \end{cases}$$

Possible differences

$$x + f_k(x) \cdot k$$

$$\oplus x + \alpha + f_k(x + \alpha) \cdot k$$

$$= \alpha + (f_k(x) + f_k(x + \alpha)) \cdot k$$

Properties of f_k

$$f_k(x) = f_k(x+k) \tag{2}$$

$$\Pr[f_k(x) = f_k(x + \alpha)] = \frac{1}{2}$$
 (2)

BISON Instantiating the Whitened Swap-Or-Not Construction
Differential Analysis

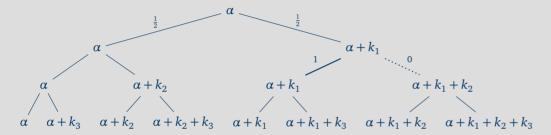

- We start by understanding the differential one round behaviour.
- For the three possible cases, let us look at what differences are actually possible.
- Remember that one round computes the output as $x + f_k(x) \cdot k$.
- With the input difference α we get as possible output differences $\beta \in \{0, \alpha, k, \alpha + k\}$.
- For decryption we need that x and x + k are mapped to the same value by f_{ν}
- Thus, $\beta = \alpha$ with probability one, if and only if $\alpha = k$ or $\alpha = 0$
- If β is not one of the above four values, such an input/output pair cannot occur, thus the probability is zero.
- For the last case, remember that for any input difference, we required that f_k collides with probability one half.

More rounds

Example differences over r = 3 rounds ($\alpha = k_1 + k_2$):

BISON Instantiating the Whitened Swap-Or-Not Construction

— Differential Analysis

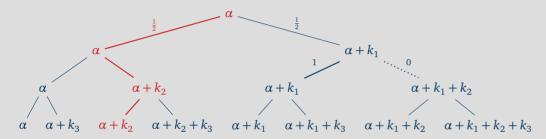

- When we look at more rounds, we can depict these cases again in this tree structure.
- Starting with the input difference α_1 assume it is different from the first round key k_0 and nonzero.
- After one round the two differences α and $\alpha + k_0$ occur with equal probability one half.
- As long as the intermediate difference is different from the next round key and nonzero, this argument iterates.
- At the point where the difference equals the next round key, these two choices collide into a deterministic propagation with probability one, where the round key is not added to the difference.

RUB

More rounds

Example differences over r = 3 rounds ($\alpha = k_1 + k_2$):

Theorem (Differentials in BISON)

Let α , $\beta \in \mathbb{F}_2^n$. Then the probability for the differential $\alpha \to \beta$ is $\Pr[\alpha \to \beta] = \sum p_\theta = p_{(\alpha,\theta_1,\dots,\theta_{r-1},\beta)}$.

BISON Instantiating the Whitened Swap-Or-Not 으 Construction -Differential Analysis

- When we look at more rounds, we can depict these cases again in this tree structure.
- Starting with the input difference α , assume it is different from the first round key k_0 and nonzero.
- After one round the two differences α and $\alpha + k_0$ occur with equal probability one half.
- As long as the intermediate difference is different from the next round key and nonzero, this argument iterates.
- At the point where the difference equals the next round key. these two choices collide into a deterministic propagation with probability one. where the round key is not added to the difference.
- Regarding differentials, the important observation is:
- For any input/output pair (α, β) , there is only one path.
- In other words: no branching occurs and the differential consists of a single trail only.

BISON

A concrete species

BISON Instantiating the Whitened Swap-Or-Not S Construction The concrete Instance

BISON

- Up to now we do not have specified much more then the initial WSN construction had.
- For a concrete implementation, we still need to define
 - Number of rounds
 - Key Schedule
 - Boolean function f_k
- So let us look at a concrete BISON species
- In particular, we discuss how to tackle Rationales 1 and 2.

Addressing Rationale 1

The Key Schedule

Rationale 1

Any instance must iterate at least n rounds; any set of n consecutive keys should be linearly indp.

Design Decisions

- Choose number of rounds as $3 \cdot n$
- Round keys derived from the state of LFSRs
- \blacksquare Add round constants c_i to w_i round keys

Implications

- Clocking an LFSR is cheap
- For an LFSR with irreducible feedback polynomial of degree *n*, every *n* consecutive states are linearly independent
- Round constants avoid structural weaknesses

BISON Instantiating the Whitened Swap-Or-Not Construction - The concrete Instance

Addressing Rationale 1

- Due to analysis of the alg. deg., we chose 3n rounds, see last slide.
- Deriving round keys from the states of LFSRs is efficiently implementable and fullfils our requirements for linear independent round keys.
- For those of you how attended Gregors talk at FSE:
 - While generating test vectors for the implementation we again noted some unwanted symmetries for encryptions with low hamming weight.
 - Thus we added round constants, to avoid these structural weaknesses.
 - (Sorry for fixing another cipher)

Addressing Rationale 2

The Round Function

Rationale 2

For any instance, the f_k should depend on all bits, and for any $\delta \in \mathbb{F}_2^n$: $\Pr[f_k(x) = f_k(x + \delta)] \approx \frac{1}{2}$.

Design Decisions

■ Choose $f_k : \mathbb{F}_2^n \to \mathbb{F}_2$ s.t.

$$\delta \in \mathbb{F}_2^n$$
: $\Pr[f_k(x) = f_k(x+\delta)] = \frac{1}{2}$,

that is, f_{ν} is a bent function.

■ Choose the simplest bent function known:

$$f_k(x,y) := \langle x,y \rangle$$

Implications

- Bent functions well studied
- \blacksquare Bent functions only exists for even n
- Instance not possible for every block length *n*

BISON Instantiating the Whitened Swap-Or-Not Construction 는 The concrete Instance

Addressing Rationale 2

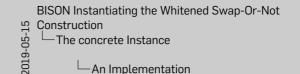

- Just chose the simplest bent function, the scalar product.
- This is also efficiently implementable.
- But, another drawback:
- Bent functions exists only for even n.
- Thus BISON cannot be instantiated for every block length n.
- In particular, due to reasons not covered here, we can actually only instantiate it for *odd* block lengths.

Construction

- $f_k(x) := ?$
- Key schedule?
- \blacksquare $\Theta(n)$ rounds?

- Coming back to our initial question.
- And basically only for the sake of completeness, as we already saw this is going to be slow.

Construction

- Key schedule: LFSRs.
- \blacksquare $\Theta(n) = 3n$ rounds.

- Coming back to our initial question.
- And basically only for the sake of completeness, as we already saw this is going to be slow.
- We have specified everything, so let's benchmark against AES (what else).

Construction

- $f_k(x,y) := \langle x,y \rangle$
- Key schedule: LFSRs.
- $\Theta(n) = 3n$ rounds.

•	Cipher	Block size (bit)	Cycles/Byte mean
	AES*	128	0.65
	BISON [†]	129	3 064.08

BISON Instantiating the Whitened Swap-Or-Not Construction 년 The concrete Instance

• Coming back to our initial guestion.

An Implementation

- And basically only for the sake of completeness, as we already saw this is going to be slow.
- We have specified everything, so let's benchmark against AES (what else).
- OK, told you so, BISON is like 4700 times slower than AES.
- Or: more than three orders of magnitude.
- Optimising this will not help enough.

^{*} AES-128 on Skylake Intel® Core i7-7800X @ 3.5GHz, see Daemen et al. [The design of Xoodoo and Xoofff, Table 5].

[†] BISON on CoffeeLake Intel® Core i7-8700 @ 3.7 GHz.

Further Cryptanalysis

Linear Cryptanalysis

For $r \ge n$ rounds, the correlation of any non-trivial linear trail for BISON is upper bounded by $2^{-\frac{n+1}{2}}$.

Invariant Attacks

For $r \ge n$ rounds, neither invariant subspaces nor nonlinear invariant attacks do exist for BISON.

Zero Correlation

For r > 2n - 2 rounds, BISON does not exhibit any zero correlation linear hulls.

Impossible Differentials

For r > n rounds, there are no impossible differentials for BISON.

Algebraic Degree and Division Property

Algebraic degree grows *linearly*. Conservative estimate: for $r \ge 3n$ rounds, no attack possible.

BISON Instantiating the Whitened Swap-Or-Not Construction Further Analysis

Further Cryptanalysis

her Cryptanalysis	RUB	
Cryptanalysis	Invariant Attacks	
n rounds, the correlation of any vial linear trail for BISON is upper and by 2 ⁻⁴² .	For r > n rounds, neither invariant subspaces nor nonlinear invariant attacks do exist for BISON.	
orrelation	Impossible Differentials	
- 2n – 2 rounds, BISON does not exhibit ro correlation linear hulls.	For r > n rounds, there are no impossible differentials for BISON.	
aic Degree and Division Property		
aic degree grows linearly. Conservative e	stimate: for $r \ge 3n$ rounds, no attack possible.	

- We did more cryptanalysis, but our results are more of the "classical" kind.
- For linear cryptanalysis, we bound the correlation of any non-trivial trail.
- Current known security arguments for resistance against invariant attacks apply.
- Zero correlation and impossible differentials do not exist for 2n rounds or more.
- Best attacks seem to exploit the algebraic degree.
- We show that it grows only linearly which is especially bad in comparison to SPN ciphers.
- The result on the algebraic degree also applies to NLFSRs or maximally unbalanced Feistel networks.
- Conservative estimation: might work for more than 2*n* rounds, but not for 3*n* or more.

Conclusion/Questions

Thank you for your attention!

BISON

- A first instance of the WSN construction
- Good results for differential cryptanalysis

Open Problems

- Construction for linear cryptanalysis?
- Similar args. for Unbalanced Feistel?

BISON Key Schedule

BISON's key schedule

Given

- primitive p_k , $p_w \in \mathbb{F}_2[x]$ with degrees n, n-1 and companion matrices C_k , C_w .
- master key $K = (k, w) \in (\mathbb{F}_2^n \times \mathbb{F}_2^{n-1}) \setminus \{0, 0\}$

The *i*th round keys are computed by

$$KS_i : \mathbb{F}_2^n \times \mathbb{F}_2^{n-1} \to \mathbb{F}_2^n \times \mathbb{F}_2^{n-1}$$

$$KS_i(k, w) := (k_i, c_i + w_i)$$

where

$$k_i = (C_k)^i k$$
, $c_i = (C_w)^{-i} e_1$, $w_i = (C_w)^i w$.
